

Prior-support diagnostic for DNN posterior inversion

DI-Weak (limited diagnostic)

DI-Strong (production control)

Dispersion MAE
(km s⁻¹)

16-84%
coverage

Pull-in ratio
(lower is better)

V_S MAE (km s⁻¹)

DI-Weak reduces support-driven boundary collapse in this diagnostic; DI-Strong remains most accurate inside its own prior support. The comparison audits prior-width bias-variance behaviour and is not a universal ranking of priors.

Pull-in is the fraction of target values outside the strong-prior envelope whose posterior medians return inside that envelope.
